ENSTA Paris

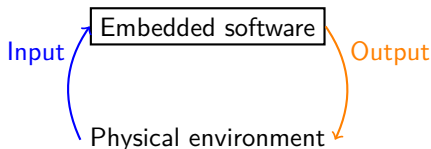

2022-2023

# Part I

## Lecture 2

# Reactive software

- **Embedded software** are also known as **reactive programs**: they continuously produce outputs in response to inputs coming from the physical environment.

- The execution of embedded software is described by **discrete-time dynamics** *i.e.* it is a sequence of reactions.

- Ideally we should have that:
  - Output  $O_i$  should be emitted before input  $I_{i+1}$  and no important input  $I_i$  is missed.
  - The software is deterministic: same input produces same output.
  - A finite amount of memory is used.

# An ideal abstraction: synchronicity

- The execution of embedded software is described by **discrete-time dynamics** *i.e.* it is a sequence of reactions.

**We assume that the computation time is zero**

- **Conceptually**
  - Output are produced infinitely quickly
  - All the computation are done in parallel
- **Verification of the hypothesis**
  - Compute WCET and check that input are not faster than WCET

# Classical implementation

A reactive software is mainly an infinite loop of the form

Two possible implementations: **sampled-base** or **event-based**

```
 $S := S_0$   
for each tick do  
  Read  $I$   
   $(S, O) = \text{step}(S, I)$   
  Write  $O$   
end for
```

```
 $S := S_0$   
for each event do  
  Read  $I$   
   $(S, O) = \text{step}(S, I)$   
  Write  $O$   
end for
```

The function *step* is the targeted applications of SCADE language

## Examples of reactive programs

Linear filters or state machines

# Model-based: kind of software targeted

SCADE function is based on

- data-flow equations
- state machines

# SCADE: Safety Critical Application Development Environment

The screenshot displays the SCADE IDE interface. The title bar reads "automate.vsw - SCADE - [mean/diagram\_mean\_1]". The menu bar includes "File", "Edit", "View", "Operator", "Insert", "Layout", "Project", "Tools", "Navigate", "Window", and "Help". The toolbar contains various icons for file operations, editing, and simulation. Below the toolbar, a "KCG" dropdown menu is visible. On the left, a "FileView" pane shows a project tree for "automate.etp" with folders for "automate", "Operators", "mean", "Interface", "diagram\_mean\_1", and "mean1". The "Interface" folder is expanded, showing variables "x", "y", and "m". The main workspace displays a block diagram with two input ports labeled "x" and "y", a central block with a plus sign and a "1" (representing a multiplier), and an output port labeled "m". A constant value "2.0" is connected to the multiplier block. The bottom status bar shows "Backup in progress...".

# Data-flow approach

A classical approach in circuits and control theory.

```
node mean (x, y : real)  
returns (m : real);  
let  
    m = (x + y) / 2;  
tel;
```

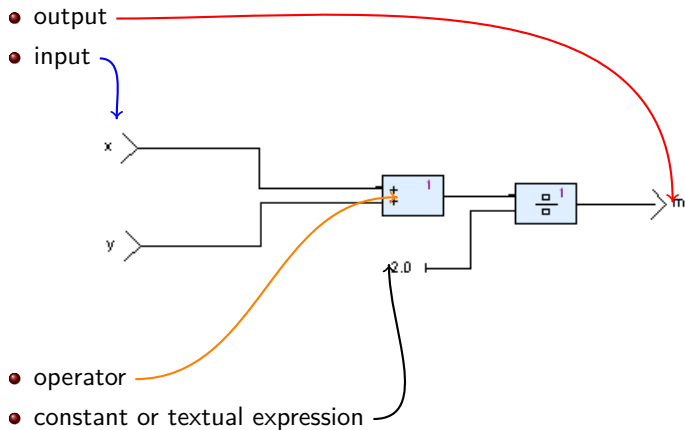

Synchronous interpretation:

$$\forall t \in \mathbb{N}, \quad m_t = (x_t + y_t)/2$$

A Lustre/SCADE program is described by a set of data-flow equations.

# Mean example in Scade

## Definition

A flow is an infinite sequence of values of the same type.

- **All the Lustre/SCADE variables** are flows.
- Type of flows: `bool`, `int8`, `int16`, `int32`, `int64`, `float32`, or `float64`.

## Flow example

- `true`  $\equiv$  `true, true, true, ...`
- `1`  $\equiv$  `1, 1, 1, ...`
- `3.14`  $\equiv$  `3.14, 3.14, 3.14, ...`

# Operations on flows

- An operator is **applied on flows** of particular type and produce an other flow of a particular type.

## Operator example

"and" is an operator applied on two Boolean flows and produces an other Boolean flow.

- Operators are applied point-wisely.

## Example

	0	1	2	3	4	5	6	7
x	true	false	true	false	true	false	true	false
y	true	true	false	true	false	false	true	true
x and y	true	false	false	false	false	false	true	false

# Example in SCADE

A set of atomic operations is offered by SCADE:

- Arithmetic

- Logical

- Comparison

**Remark:** SCADE Suite can be configured to display type variable

# Lustre/SCADE program

A Lustre/SCADE program is made of a set of equations such that:

- **The order of equations is not important**
- **follows the substitution principle**

## Example

```
node nand (x, y: bool) returns (z: bool);  
var u: bool;  
let  
  z = not u;  
  u = x and y;  
tel
```

Execution:	x	true	true	false	true	true	false	...
	y	false	true	false	false	true	false	...
	u	false	true	false	false	true	false	...
	z	true	false	true	true	false	true	...

## Example in SCADE

# Main language construction

Mathematical	
Logical	
Structure/Array	
Higher Order	
Comparison	
Time	
Choice	

## Example

```
node max (x, y: int) returns (m: int);  
let  
    m = if (a >= b) then a else b;  
tel
```

**Remark:** if expression as in functional language

- $\text{if}: (\text{bool flow}) \times (\text{t flow}) \times (\text{t flow}) \rightarrow (\text{t flow})$

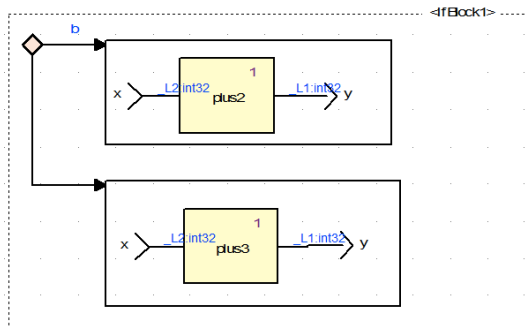

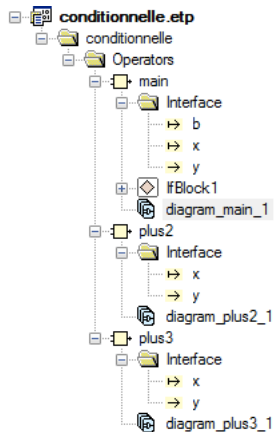

**Remark:** always **then** and **else**  $\Rightarrow$  **determinism**.

## Example in SCADE

# if block

Solve the initialisation problem of pre operator by fixing the initial value.

$$(x -> y)_i = \begin{cases} x_i & \text{if } i = 0 \\ y_i & \text{if } i > 0 \end{cases}$$

- **Warning** the **dates**  $i$  **are absolute** and not relative to the current instant.

### Example

$x$		1	1	1	0	...
$0 -> x$		0	1	1	0	...

What is the value of:  $0 -> (0 -> 1)$ ?

- pre: retains in memory previous values of a flow.

$$(\text{pre}(e))_i = \begin{cases} \perp & \text{if } i = 0 \\ e_{i-1} & \text{if } i > 0 \end{cases}$$

**Memory size:** number of embedded pre operators.

## Example

e		1	0	1	0	1	...
pre e		$\perp$	1	0	1	0	...

**Remark:** Initialisation problem of pre operator which solves using  $\rightarrow$  operator.

## Example: min and max

### min/max program

```
node minmax (x: int)  
returns (min, max: int);  
let  
  min = x  $\rightarrow$  if (x < pre(min)) then x else pre(min);  
  
  max = x  $\rightarrow$  if (x > pre(max)) then x else pre(max);  
tel
```

### Execution:

x	12	5	7	-2	21	0	...
min	12	5	5	-2	-2	-2	...
max	12	12	12	12	21	21	...

# fbby (followed by) operator

## Idea

Combination of the two operators: `pre` and `->`

## Syntax

`fbby(exp; delay; init )`

- `exp`: flow expression;
- `delay`: number of delay instants;
- `init`: initial values.

## Example

`y = fbby(x;1;0) + 1;`

equivalent to

`y = (0 -> pre(x)) + 1;`

# Definition of recursive flows

Corrects definition

- The sequence of values can be defined step by step
- *i.e.*, the recursion is not related to the past
- *i.e.*, no short circuit:  
e.g., equation  $x = x + 1$  has no solution  
**Remark:** in some cases the recursion has a solution  
e.g.,  $x = 1/(2 - x)$   
but the computation is unbounded.

## Example of recursive flows

`alt = false -> not pre alt`

⇒ built flow: false true false true ...

# A graphical representation

Lustre/SCADE is mostly used with this graphical representation

its textual representation

```
count = fby(count + if incr then 1 else 0; 1; 0)
```

# SCADE operator (Lustre node)

- **Equations** define the **output values** by constraining the input flows.
- Instantaneous evaluation and the order of equations is not important
- the value of output flow must be uniquely defined.

## Node example

```
node voter (e1, e2, e2: bool) returns (s: bool);
var tmp1, tmp2: bool;
let
  tmp1 = e1 and e2;
  s = tmp1 or (e1 and tmp2);
  tmp2 = e2 or e3;
tel
```

# Operator hierarchy

## Remark

Only one root to be defined at compile time

# Operator semantics

- A Lustre/SCADE node is a specification of constraints between input and output flows.
- The semantics of one node is then a set of input and output flows which are admissible for these constraints.
- Every node defined by the user can be reuse.

## Remark

a node without state should be declared as a function.

## Example

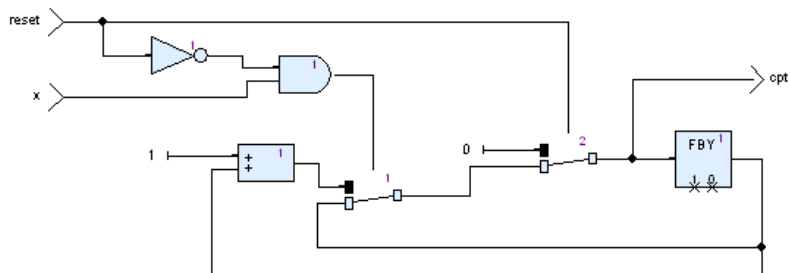

- the input flow  $X$  is taken into account only if it is maintained more than  $n$  hundredths of a second;
- the input flow  $cs$  is true each hundredth of a second.
- the output flow  $y$  is true when the input  $X$  is maintained more than  $n$  hundredths of a second;

# Example - 1

Two nodes are needed:

- CounterReset: increases a counter when X is true and it is reset when reset (priority) is true;
- Detector:

## CounterReset node

## Example - 2

Two nodes are needed:

- CounterReset: increases a counter when X is true and it is reset when reset (priority) is true;
- Detector:

### Detector node

# Clocks and sampling operator

Sampling operator: `when`  
uses to define a slower rate flow than its output.

## Example of sampling

X	4	1	-3	0	2	7	8	...
C	true	false	false	true	true	false	true	...
X when C	4			0	2		8	...

**Remark:** when C is false, X when C **does not exist**.

**Warning:** operators are applied on flows on the same clock.  
*e.g.,  $x + (x \text{ when } c)$  is not allowed*

**Remark 2:** we can sample a sampled flow.

```
node cpt (x: bool) returns (y: int);  
var cpt: int;  
let  
  y = 0  $\rightarrow$  if x then pre cpt + 1 else pre cpt  
end
```

- Sampling input is not equivalent to sampling output.

## Sampling examples

C	true	true	false	false	true	false	...
cpt (true when C)	0	1			2		...
cpt (true) when C	0	1			4		...

# merge operator

Bring back a low rate flow on a faster clock.

## Definition

$$\text{merge}(h; x^1; \dots; x^p) = \begin{cases} x_n^1 & \text{if } h \text{ match } e^1 \\ \vdots & \\ x_n^p & \text{if } h \text{ match } e^p \end{cases}$$

$h$  is an element of enumerated type among  $e^1, \dots, e^p$ .

## Projection example

X	2	-2	2	-2	2	-2	2	...
Y	-1	1	-1	1	-1	1	-1	...
C	true	false	false	true	true	false	true	...
U = X when C	2			-2	2		2	...
V = Y when not C		1	-1			1		...
N = merge(C;U;V)	2	1	-1	-2	2	1	2	...

# Conditional activation of an operator

## Definitions

- **activate** N **every** clock\_expr  
N is activated when clock clock\_expr is true.
- **activate** N **every** clock\_expr **default** exp  
Idem except that the value of expr2 is returned when clock\_expr is false.
- **activate** N **every** clock\_expr **initial** **default** exp  
N is activated when clock\_expr is true. And when clock\_expr is false the result is set with the value of expr2 at the first instant then it is the latest value of N which is used.

```
node integr (X: int) retruns (Y: int)  
let  
  Y = X + (0 -> pre(Y));  
tel
```

# Conditional activation of an operator

## Definitions

- **activate** N **every** clock\_expr  
N is activated when clock clock\_expr is true.
- **activate** N **every** clock\_expr **default** exp  
Idem except that the value of expr2 is returned when clock\_expr is false.
- **activate** N **every** clock\_expr **initial** **default** exp  
N is activated when clock\_expr is true. And when clock\_expr is false the result is set with the value of expr2 at the first instant then it is the latest value of N which is used.

## Example

t = activate(integr every C) (X)

X	1	2	3	4	5	6	...
C	false	true	false	false	true	true	...
t		2			7	13	...

# Conditional activation of an operator

## Definitions

- **activate** N **every** clock\_expr  
N is activated when clock clock\_expr is true.
- **activate** N **every** clock\_expr **default** exp  
Idem except that the value of expr2 is returned when clock\_expr is false.
- **activate** N **every** clock\_expr **initial** **default** exp  
N is activated when clock\_expr is true. And when clock\_expr is false the result is set with the value of expr2 at the first instant then it is the latest value of N which is used.

## Example

t = activate(integr every C default 0) (X)

X	1	2	3	4	5	6	...
C	false	true	false	false	true	true	...
t	0	2	0	0	5	11	...

# Conditional activation of an operator

## Definitions

- **activate** N **every** clock\_expr  
N is activated when clock clock\_expr is true.
- **activate** N **every** clock\_expr **default** exp  
Idem except that the value of expr2 is returned when clock\_expr is false.
- **activate** N **every** clock\_expr **initial** **default** exp  
N is activated when clock\_expr is true. And when clock\_expr is false the result is set with the value of expr2 at the first instant then it is the latest value of N which is used.

## Example

t = activate(integr every C initial default 0) (X)

X	1	2	3	4	5	6	...
C	false	true	false	false	true	true	...
t	0	2	2	2	5	11	...

# Conditional activation of a set of equations

## Definition

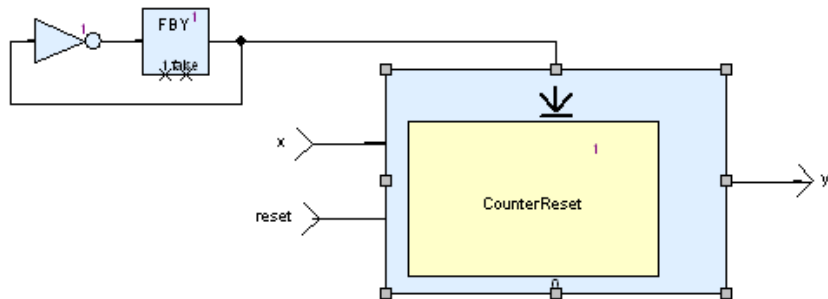

- **activate if** *exp* **then** *equation\_set1* **else** *equation\_set2*;  
If *expr* is true then *equation\_set1* is evaluated else *equation\_set2* is evaluated.

## Example

```
node N (e:int; h:bool) returns (s: int; t:int last=0)
let
  s = integr(e);
  activate if h then t = integr(e); else t = last 't;
  returns t;
tel
```

e	1	2	3	4	5	6	7	...
h	false	true	false	false	true	true	false	...
s	1	3	6	10	15	21	28	...
t	0	2	2	2	7	13	13	...

## Example of activated node

## Definition

- **(restart N every c)(e);**  
is used to set the node N in its initial state.

## Example

```
node S (e: int) returns (sum: int)  
  let sum = 0 -> e + pre sum; tel
```

```
node Count () returns (x: int)  
  let x = 0 -> (1 + pre(x)); tel
```

```
s = (restart S every (0 -> pre s >= 10)) (Count());
```

Count()	0	1	2	3	4	5	6	7	8	9	...
s	0	1	3	6	10	0	6	13	0	9	...
